## **Part1: 8-Channel AD Acquisition Module Parameters**

AN706 8-Channel AD Acquisition module detail parameter listed as below:

- Module VPN: AN706
- AD Chip: AD7606
- Channel: 8-channel
- AD bits: 16-bit
- Max Sample Rate: 200KSPS
- Input Voltage Rate: -5V~+5V
- PCB layers of Module: 4-Layer, independent power layer and GND layer
- Module Interface: 40-pin 0.1 inch spacing female header, download direction
- Ambient Temperature (with power applied: -40°~85°, all the chips on module to meet the industrial requirements
- Input interface: 8 SMA interfaces and 16-pin headers with 2.54 pitch (Pin Each channel has positive and negative two Pin)
- Measurement accuracy: Within 0.5mV

## Part 2 AN706 Module Block Diagram

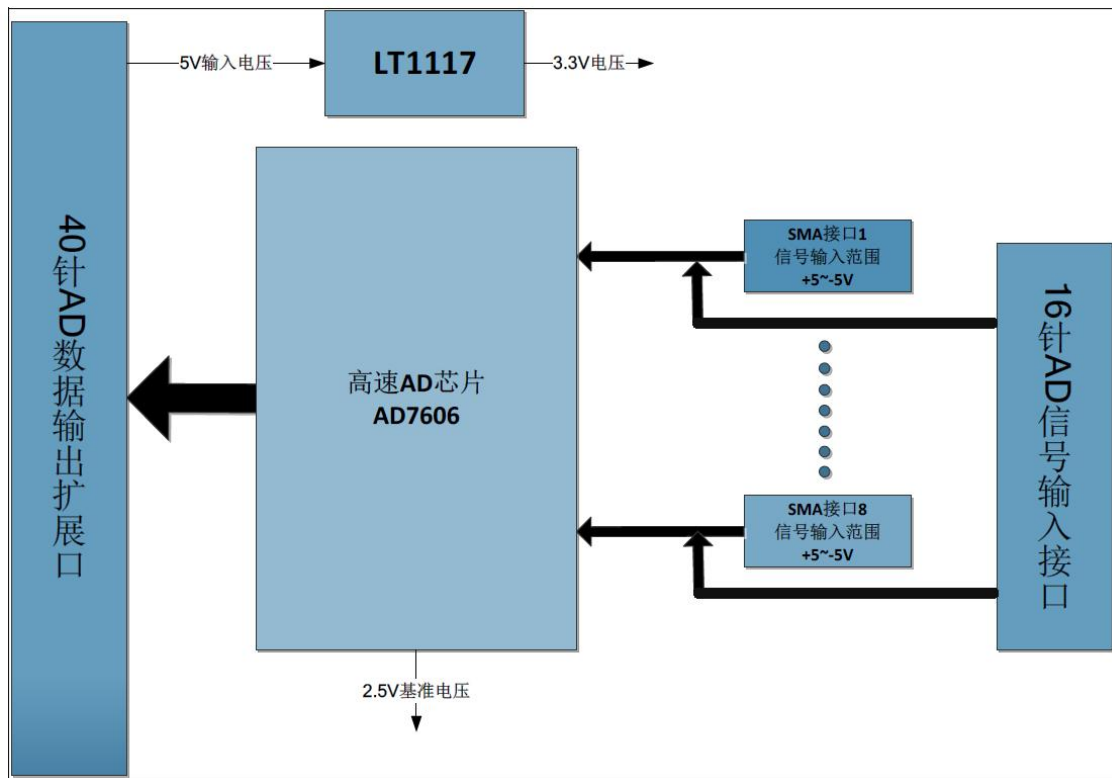

Figure 2-1: AN706 Module Block Diagram as below:

## Part 3: AD7606 Chip Introduction

The AD7606 is an integrated 8-channel simultaneous sampling data acquisition system with on-chip input amplifiers, overvoltage protection circuitry, a second-order analog antialiasing filter, an analog multiplexer, a 16-bit 200 kSPS SAR ADC, and a digital filter, 2.5 V reference, reference buffer, and high-speed serial and parallel interfaces.

The AD7606 operates from a single +5V supply and can handle  $\pm 10V$  and  $\pm 5V$  true bipolar input signals while sampling at throughput rates up to 200KSPS on all channels. The input clamp protection circuit can tolerate voltages up to  $\pm 16.5V$ .

The AD7606 has 1 M $\Omega$  analog input impedance regardless of sampling frequency. The single supply operation, on-chip filtering, and high input impedance eliminate the need for driver op amps and external bipolar supplies.

The AD7606/AD7606-6/AD7606-4 antialiasing filter has a 3 dB cutoff frequency of 22 kHz and provides 40 dB antialias rejection when sampling at 200 kSPS. The flexible digital filter is pin driven, yields improvements in SNR, and reduces the 3 dB bandwidth.

## Part 5: AD7606 Chip Timing Specification

AD7606 channel with simultaneous sampling, using parallel mode

The AD7606 can simultaneously sample all 8 analog input channels. When the two CONVST pins (CONVSTA and CONVSTB) are tied together, all channels are sampled simultaneously. The rising edge of this shared CONVST signal initiates simultaneous sampling of all analog input channels (V1 to V8).

The AD7606 contains an on-chip oscillator for conversion. The conversion time for all ADC channels is  $t_{CONV}$ . The BUSY signal informs the user that a conversion is in progress, so when the rising edge of CONVST is applied, BUSY goes to logic high and goes low at the end of the entire conversion process. The falling edge of the BUSY signal is used to return all eight track-and-hold amplifiers to track mode. The falling edge of BUSY also indicates that 8 channels of data can now be read from the parallel bus DB[15:0].

## Part 6: AD7606 Chip Pin Configuration

In the AN706 8-channel AD module hardware circuit design, we set the AD7606's operating mode by adding pull-up or pull-down resistors to the three configuration pins of the AD7606.

- 1) The AD7606 supports an external reference input or an internal reference. If an external reference is used, the REFIN/REFOUT of the chip requires an external 2.5V reference. If using an internal reference voltage. The REFIN/REFOUT pin is an internal 2.5V reference. The REF SELECT pin is used to select the internal reference or external reference. In this module, because the accuracy of the internal reference voltage of the AD7606 is also very high (2.49V~2.505V), the circuit design chooses to use the internal reference voltage.

Pin Name	Set level	Description
REF SELECT	High Level	Use internal reference voltage 2.5V

- 2) The AD7606's AD conversion data acquisition can be in parallel mode or serial mode. The user can set the communication mode by setting the PAR/SER/BYTE SEL pin level. in the AN706 module design, select parallel mode to read AD data of AD7606

Pin Name	Set level	Description
PAR/SER/BYTE SEL	Low Level	Select parallel interface

- 3) The RANGE pin is used to select either  $\pm 10$  V or  $\pm 5$  V as the input range in AD9767. In the  $\pm 5$  V range, 1LSB=152.58uV. In the  $\pm 10$  V range, 1LSB=305.175 uV. In the circuit design of AN706 module, select  $\pm 5$ V analog voltage input range

Pin Name	Set level	Description
RANGE	Low Level	Analog signal input range selection: $\pm 5$ V

- 4) The AD7606 contains an optional digital first-order sinc filter that should be used in applications where slower throughput rates are used or where higher signal-to-noise ratio or dynamic range is desirable. The oversampling

ratio of the digital filter is controlled using the oversampling pins, OS [2:0] (see Table below). OS 2 is the MSB control bit, and OS 0 is the LSB control bit. Table below provides the oversampling bit decoding to select the different oversample rates. The OS pins are latched on the falling edge of BUSY.

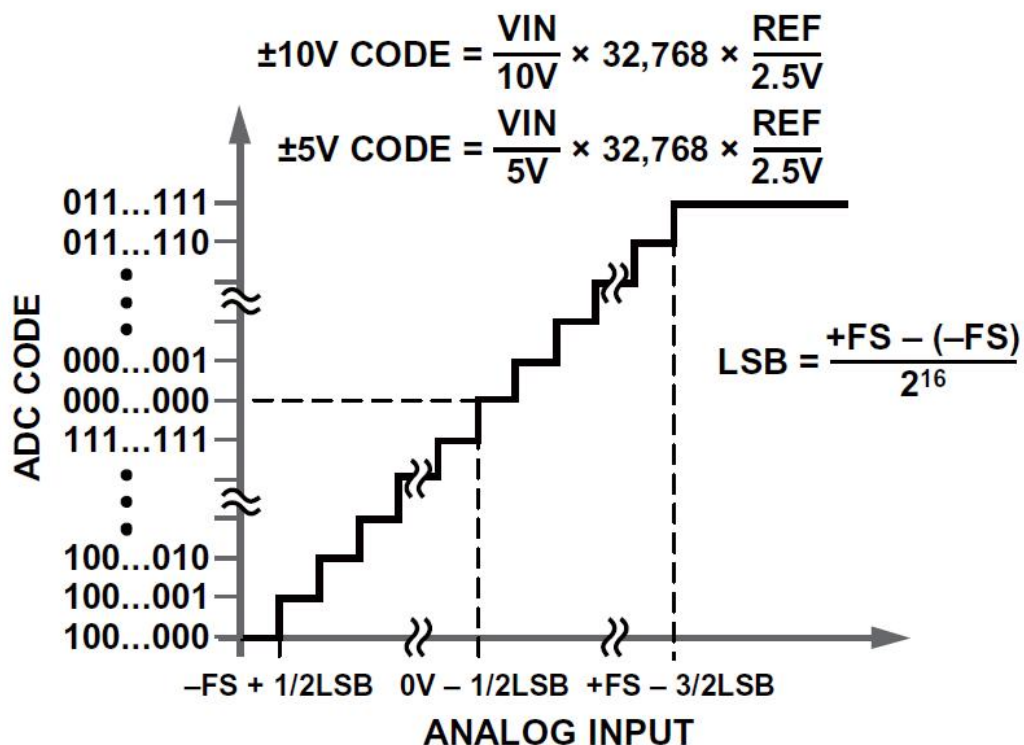

表9. 过采样位解码

OS[2:0]	过采样 倍率	5 V范围SNR(dB)	10 V范围SNR(dB)	5 V范围3 dB带宽 (kHz)	10 V范围3 dB带宽 (kHz)	最大吞吐量CONVST频率(kHz)

110	64	96.9	97	1.5	1.5	3.125

In the hardware design of the AN706 module, OS[2:0] leads to the external interface, and the FPGA or CPU can select whether to use the filter by controlling the pin level of OS[2:0] to achieve higher measurement accuracy.

## Part 7: AD7606 Chip ADC TRANSFER FUNCTION

The output coding of the AD7606 is two's complement. The designed code transitions occur midway between successive integer LSB values, that is,  $1/2$  LSB and  $3/2$  LSB. The LSB size is  $FSR/65,536$  for the AD7606. The ideal transfer characteristic for the AD7606 is shown in Figure 7-1.

	+FS	MIDSCALE	-FS	LSB

## Part 9: AN706 Module Experimental Procedure

- 1) First, connect the AN706 module to the 34-pin standard expansion port of the ALINX FPGA Development Board (In case the development board is powered off).
- 2) Connect your signal source to the AN706 Module input connector (**Note: AD port input range: -5V~+5V**).
- 3) Download the program to the FPGA using the Quartus II or ISE software (if you need the testing programs, send email to [rachelhust@163.com](mailto:rachelhust@163.com)).
- 4) Open the serial debugging assistant tool and set the communication baud rate of the serial port as follows

- 5) The voltage value of the 8-channel signal input of the AN706 module will appear in the serial communication. (Because the 8-way data is displayed in one line in the serial debugging assistant, we need to enlarge the interface.)

The above data is 8 channels of data without signal input, because the AD signal input is in a floating state, and the AD conversion output data is about 1.75V.

**Example:** If you connect the input of channel 1 with the 3.3V test pin on the AN706 module with a DuPont line to test the voltage of 3.3V on the module.

Figure 9-3: Channel 1 with 3.3V test pin

At this time, the measurement data of AD1 displayed on the serial interface is about +3.3074.

Figure 9-4: Test pin voltage display on the serial interface

## Part 10: AN706 Module Measurement Accuracy

By measuring the applied voltage and the high-precision voltmeter, the actual measurement accuracy of the AD706 module is within 0.5mV within the -5V to +5V voltage input range.

The following table shows the results of eight channels for four analog voltages. The first column is the data measured by the high-precision digital multimeter, and the last eight columns are the results of the AD module's AD module measurement.

Table 10-1: Testing Voltage

In this test routine, the oversampling override enable filter is not used to improve the accuracy of the AN706 module. For users who want to further improve the accuracy of sampling and the sampling speed is not high, it can be set in the program. Method of sampling magnification, you can set the oversampling ratio in the program.

## Part 11: AN706 Module Test Program Description

The following is a brief description of the ideas for each Verilog test programs, and users can also refer to the note description in the code.

### 1. Top level program: ad706\_test.v

Define the FPGA and AN706 modules and the serial port to receive and send the signal input and output, and instantiate three subroutines (ad7606.v, volt\_cal.v and uart.v).

### 2. AD data acquisition program: ad7606.v

According to the timing of AD7606, 8 channels of analog signals are sampled, and the 16-bit data after AD conversion. The program first transmits the CONVSTAB signal to AD7606 to start AD data conversion, waits for the Busy signal to be low and then reads the data from AD channel 1 to channel 16 in sequence.

### **3. Voltage conversion program for AD data: volt\_cal.v**

The program converts the 16-bit data collected from ad7606.v, Bit[15] to positive and negative symbols, and Bit[14:0] first converts it into a voltage value by the following formula, and then converts the hexadecimal voltage value into 20-digit BCD code.

$$\text{AD Voltage Conversion (1 LSB)} = 5V / 32758 = 0.15 \text{ mV}$$

### **4. Serial port sending program: uart.v**

Timing transmits 8 channels of voltage data to the PC through uart. The serial port's transmit clock is obtained by dividing the frequency by 50Mhz, and the baud rate is 9600bps.
